## Summary

# Diagonalizable matrix

## Definition

If  $B = S^{-1}DS$  where  $D$  is a diagonal matrix then  $B$  is diagonalizable.

## Motivation.

Using elementary row operations we want to turn  $B\mathbf{x} = \mathbf{y}$  into  $D\hat{\mathbf{x}} = \hat{\mathbf{y}}$ . This can be written as  $SB\mathbf{x} = S\mathbf{y}$ . Since elementary row operations are invertible  $SBS^{-1}S\mathbf{x} = S\mathbf{y}$ . Let  $\hat{\mathbf{x}} = S\mathbf{x}$  and  $\hat{\mathbf{y}} = S\mathbf{y}$ , then

$$D = SBS^{-1} \Leftrightarrow B = S^{-1}DS$$

Summary

# Hessenberg matrix

- ▶ 'Almost' triangular
- ▶ Multiplication of a (upper) Hessenberg matrices and a (upper) triangular matrix gives a new Hessenberg matrix (Useful in for example the QR-method used to find eigenvalues of a matrix).
- ▶ Diagonal elements usually give a rough approximation of the eigenvalues.

# Hermitian matrix

## Definition

The *Hermitian conjugate* of a matrix  $A$  is denoted  $A^H$  and is defined by  $(A^H)_{ij} = \overline{(A)_{ji}}$ .

## Definition

A matrix is said to be *Hermitian* (or *self-adjoint*) if  $A^H = A$ .

Summary

# Properties of unitary matrices

## Theorem

Let  $U$  be a unitary matrix, then

- $U$  is always invertible.
- $U^{-1}$  is also unitary.
- $|\det(U)| = 1$
- $(UV)^H = (UV)^{-1}$  if  $V$  is also unitary.
- For any  $\lambda$  that is an eigenvalue of  $U$ ,  $\lambda = e^{i\omega}$ ,  $0 \leq \omega \leq 2\pi$ .
- Let  $\mathbf{v}$  be a vector, then  $\|U\mathbf{v}\| = \|\mathbf{v}\|$  (for any vector norm).
- The rows/columns of  $U$  are *orthonormal*, that is  $U_i \cdot U_j^H = 0$ ,  $i \neq j$ ,  $U_k \cdot U_k^H = 1$ .
- $U$  preserves eigenvalues.

# Example of a unitary matrix

- ▶ The C matrix below rotates a vector by the angle  $\theta$  around the  $x$ -axis

$$C = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos(\theta) & -\sin(\theta) \\ 0 & \sin(\theta) & \cos(\theta) \end{bmatrix}$$

and is a unitary matrix.

# Positive definite matrix

## Definition

We consider a square symmetric real valued  $n \times n$  matrix  $A$ , then:

- ▶  $A$  is positive definite if  $\mathbf{x}^\top A \mathbf{x}$  is positive for all non-zero vectors  $\mathbf{x}$ .
- ▶  $A$  is positive semidefinite if  $\mathbf{x}^\top A \mathbf{x}$  is non-negative for all non-zero vectors  $\mathbf{x}$ .
- ▶  $A$  is *positive definite*  $\Leftrightarrow \lambda > 0$  for all  $\lambda$  eigenvalue of  $A$ .
- ▶ Can also define negative definite and semi-definite matrices.

Summary

# Positive definite matrix

Positive definite matrices have many useful properties, if  $A$  is positive definite then

- ▶  $A$  is invertible.
- ▶  $A$  have a unique cholesky decomposition (seen later today).
- ▶ Positive definite matrices are closely related to quadratic forms (last lecture).
- ▶ Any Covariance matrix is positive semi-definite.

## Summary

# Spectral factorization

- ▶ Spectral factorization is a special version of diagonal factorization.
- ▶ It is sometimes referred to as *eigendecomposition*.
- ▶ Let  $A$  be an square ( $n \times n$ ) matrix with linearly independent rows. Then

$$A = Q\Lambda Q^{-1}$$

where  $AQ_{.i} = \Lambda_{ii}Q_{.i}$  for all  $1 \leq i \leq n$ .

Summary

# Cholesky factorization

- ▶ Systems involving triangular matrices are often easy to solve.
- ▶ Try to rewrite a matrix as a product that contains a triangular matrix seems like a good idea.
- ▶ One way is using  $LU$ -factorization where  $PA = LU$  where  $P$  is a permutation matrix,  $L$  is a lower- and  $U$  is an upper triangular matrix.
- ▶ There is also the Cholesky factorization,  $A = GG^H$ , where  $A$  is *Hermitian* and *positive-definite* and  $G$  is lower triangular.

# Cholesky factorization

- ▶ Consider the equation  $Ax = y$ . If  $A$  can be Cholesky factorized,  $A = GG^H$ , this equation can be turned into two new equations:

$$\begin{cases} Gz = y \\ G^H x = z \end{cases}$$

both of these equations are easy to solve.

Summary

# Calculating the Cholesky factorization

Looking at the relation  $A = LL^T$  for a real positive definite  $3 \times 3$  matrix we get:

$$A = \begin{bmatrix} L_{1,1} & 0 & 0 \\ L_{2,1} & L_{2,2} & 0 \\ L_{3,1} & L_{3,2} & L_{3,3} \end{bmatrix} \begin{bmatrix} L_{1,1} & L_{2,1} & L_{3,1} \\ 0 & L_{2,2} & L_{3,2} \\ 0 & 0 & L_{3,3} \end{bmatrix}$$
$$= \begin{bmatrix} L_{1,1}^2 & L_{2,1}L_{1,1} & L_{3,1}L_{1,1} \\ L_{2,1}L_{1,1} & L_{2,1}^2 + L_{2,2}^2 & L_{3,1}L_{2,1} + L_{3,2}L_{2,2} \\ L_{3,1}L_{1,1} & L_{3,1}L_{2,1} + L_{3,2}L_{2,2} & L_{3,1}^2 + L_{3,2}^2 + L_{3,3}^2 \end{bmatrix}$$

# Calculating the Cholesky factorization

Since  $A$  is symmetric we only need to calculate the lower triangular part.

$$\begin{bmatrix} L_{1,1}^2 & - & - \\ L_{2,1}L_{1,1} & L_{2,1}^2 + L_{2,2}^2 & - \\ L_{3,1}L_{1,1} & L_{3,1}L_{2,1} + L_{3,2}L_{2,2} & L_{3,1}^2 + L_{3,2}^2 + L_{3,3}^2 \end{bmatrix}$$

- For the elements  $L_{i,j}$  we get:

$$L_{j,j} = \sqrt{A_{j,j} - \sum_{k=1}^{j-1} L_{j,k}^2}$$

$$L_{i,j} = \frac{1}{L_{j,j}} \left( A_{i,j} - \sum_{k=1}^{j-1} L_{i,k}L_{j,k} \right), \quad i > j$$

- We notice that we only need the elements above and to the left to calculate the next element.

# Applications of Cholesky factorization

- ▶ Are there any interesting matrices that can be easily Cholesky factorized?
- ▶ Any covariance matrix is positive-definite and any covariance matrix based on measured data is going to be symmetric and real-valued. From the last two properties it follows that this matrix is Hermitian.
- ▶ Example application: generating variates according to a multivariate distribution with covariance matrix  $\Sigma$  and expected value  $\mu$

Using the Cholesky factorization you get the simple formula  $X = \mu + G^T Z$  where  $X$  is the variate,  $\Sigma = GG^H$  and  $Z$  is a vector of standard normal variates.

# QR factorization

## Theorem

Every  $n \times m$  matrix  $A$  have a matrix decomposition

$$A = QR$$

where

- ▶  $R$  is a  $n \times m$  upper triangular matrix..
- ▶  $Q$  is a  $n \times n$  unitary matrix.

Summary

# QR factorization

- ▶ Given a QR-factorization we can solve a linear system  $Ax = b$  by solving  $Rx = Q^{-1}b = Q^H b$ . Which is can be done fast since R is a triangular matrix.
- ▶ QR-factorization can also used in solving the linear least square problem.
- ▶ It plays an important role in the QR-method used to calculate eigenvalues of a matrix numerically.

# Canonical form

- ▶ A *canonical form* is a standard way of describing an object.
- ▶ There can be several different kinds of canonical forms for an object.
- ▶ Some examples for matrices:
  - ▶ Diagonal form (for diagonalizable matrices)
  - ▶ Reduced row echelon form (for all matrices)
  - ▶ Jordan canonical form (for square matrices)
  - ▶ Singular value factorization form (for all matrices)

# Reduced row echelon form

## Definition

A matrix is written on *reduced row echelon form* when they are written on echelon form and their pivot elements are all equal to one and all other elements in a pivot column are zero.

$$B = \begin{bmatrix} 0 & 1 & * & 0 & 0 & 0 & * & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & * & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & * & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & * & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

Summary

# Jordan normal form

## Theorem

*All square matrices are similar to a Jordan matrix. The Jordan matrix is unique except for the order of the Jordan blocks. This Jordan matrix is called the Jordan normal form of the matrix.*

## Theorem (Some other interesting properties of the Jordan normal form)

*Let  $A = S^{-1}JS$*

- a) *The eigenvalues of  $J$  is the same as the diagonal elements of  $J$ .*
- b)  *$J$  has one eigenvector per Jordan block.*
- c) *The rank of  $J$  is equal to the number of Jordan blocks.*
- d) *The normal form is sensitive to perturbations. This means that a small change in the normal form can mean a large change in the  $A$  matrix and vice versa.*

# Singular value factorization

## Theorem

All  $A \in \mathcal{M}_{m \times n}$  can be factorized as

$$A = U\Sigma V^H$$

where  $U$  and  $V$  are unitary matrices and

$$\Sigma = \begin{bmatrix} S_r & 0 \\ 0 & 0 \end{bmatrix}$$

where  $S_r$  is a diagonal matrix with  $r = \text{rank}(A)$ . The diagonal elements of  $S_r$  are called the singular values. The singular values are uniquely determined by the matrix  $A$  (but not necessarily their order).

Similar matrices

## Summary

# Similar matrices

- ▶ In everyday language two matrices are 'similar' if they have almost the same elements or structure. But there is also a precise mathematical relation between two matrices that is called similar.

## Definition

Two matrices,  $A$  and  $B$ , are *similar* if  $A = S^{-1}BS$ .

# Interesting properties of similar matrices

- ▶ Similar matrices share several properties:
  - ▶ Eigenvalues (but generally not eigenvectors)
  - ▶ Determinant
  - ▶ Trace
  - ▶ Rank
- ▶ We have already seen some examples of why similar matrices are interesting:
  - ▶ Diagonalizable matrices  $A = S^{-1}BS$
  - ▶ Permutation matrices  $A = PBP^T$
  - ▶ Jordan normal form  $A = S^{-1}JS$
- ▶ Similarity between matrices mean they represent the same linear mapping described in different basis.

# Summary

- ▶ Triangular and Hessenberg matrices
- ▶ Hermitian matrices
- ▶ Unitary matrices
- ▶ Positive definite matrices

# Summary

- ▶ Matrix factorization
  - ▶ Spectral factorization  $Q\Lambda Q^{-1}$
  - ▶  $LU$ -factorization
  - ▶ Cholesky factorization  $GG^H$
  - ▶  $QR$ -factorization
  - ▶ Rank factorization  $CF$
  - ▶ Jordan canonical form  $S^{-1}JS$
  - ▶ Singular value factorization  $U\Sigma V^H$
